Creating the project :

Name : E-commerce Platform

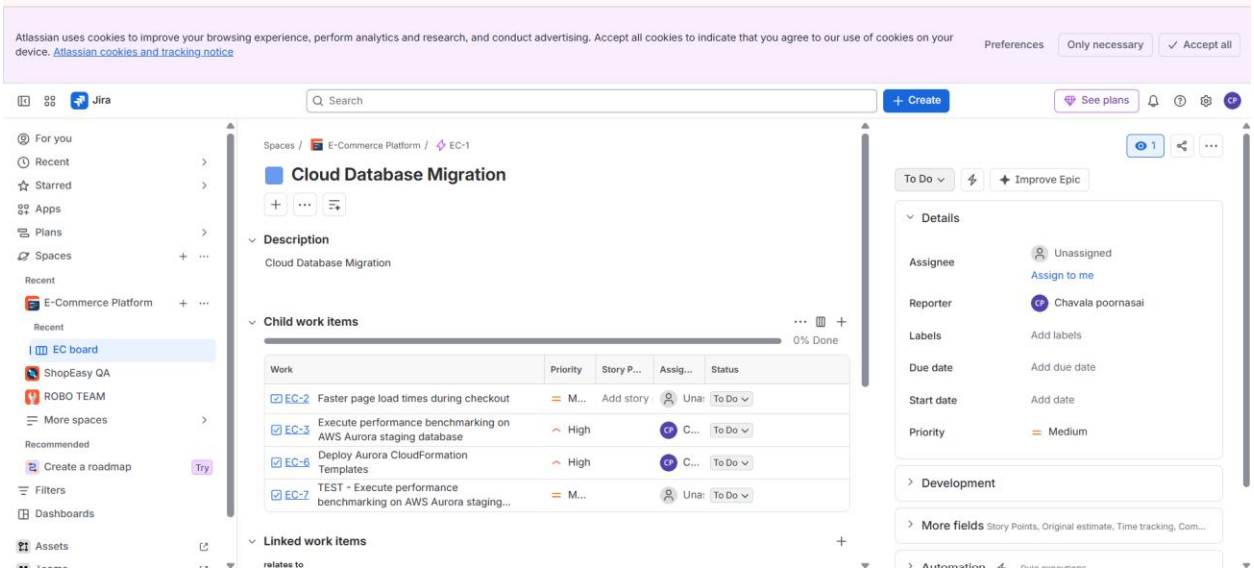

EC BOARD :

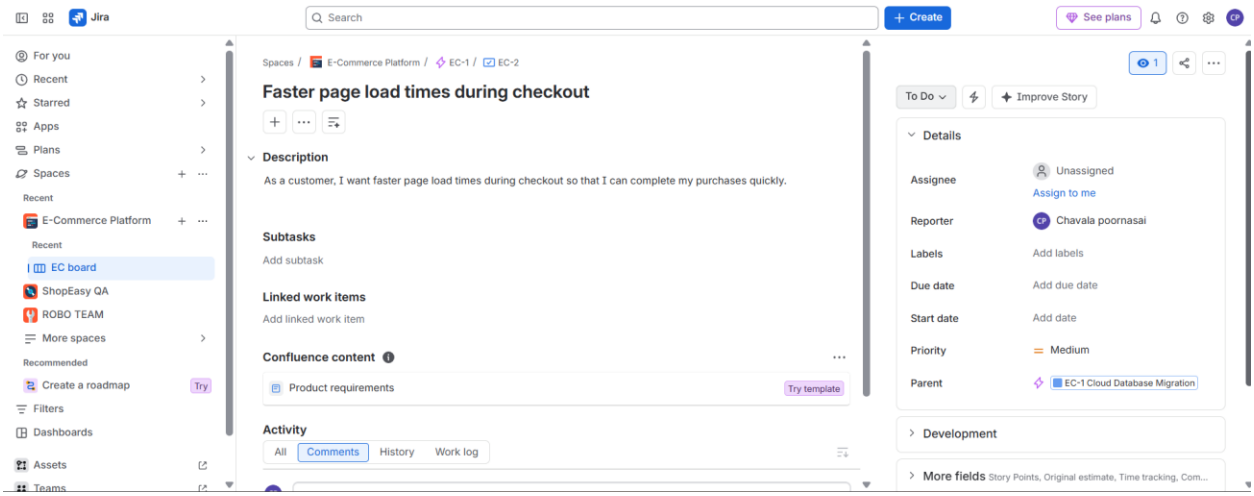

Created Epic :

Name : Cloud Database Migration

Created User Story :

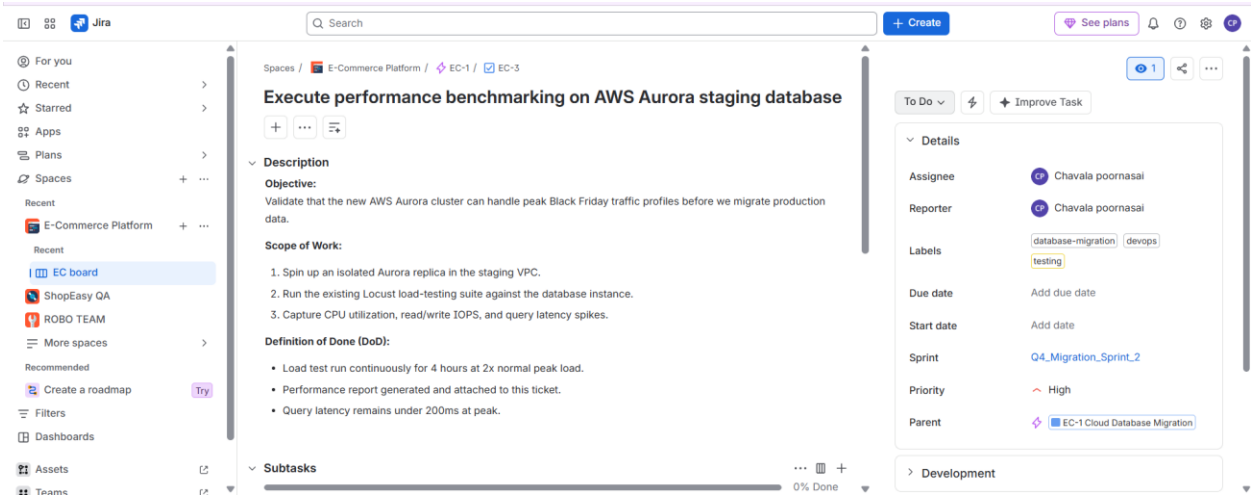

Name: Faster page load times during checkout

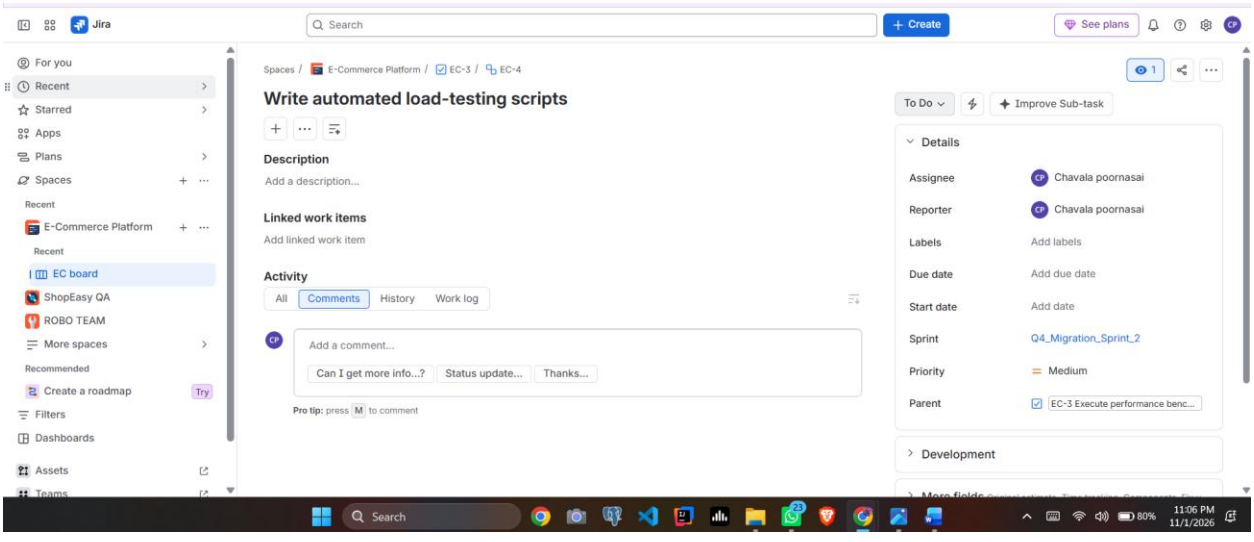

Created Task :

Name : Execute performance benchmarking on AWS Aurora staging database

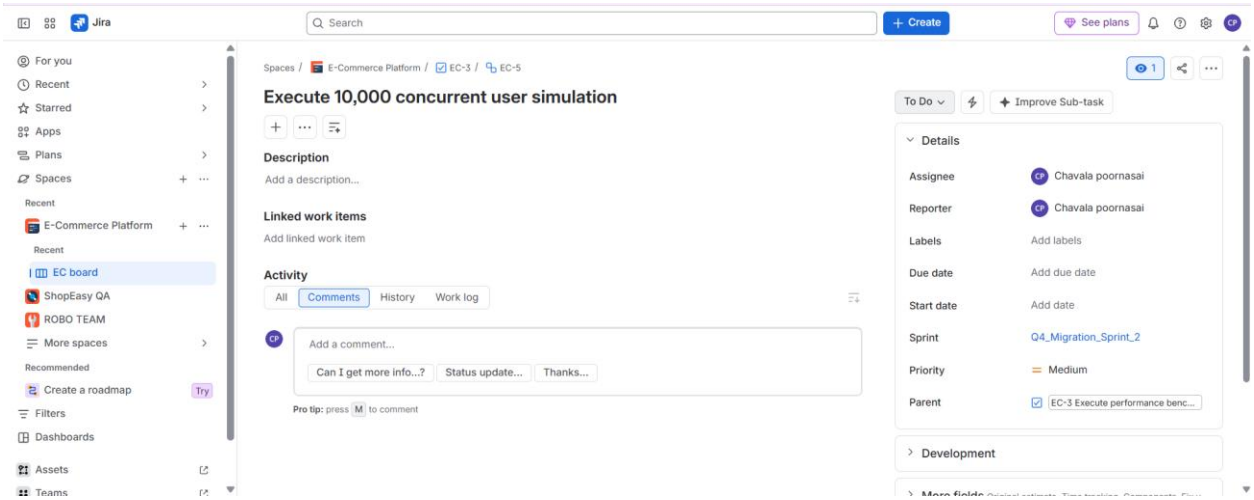

Scope of work , Definition of Done .

Manually added Sub task -1 to the above task:

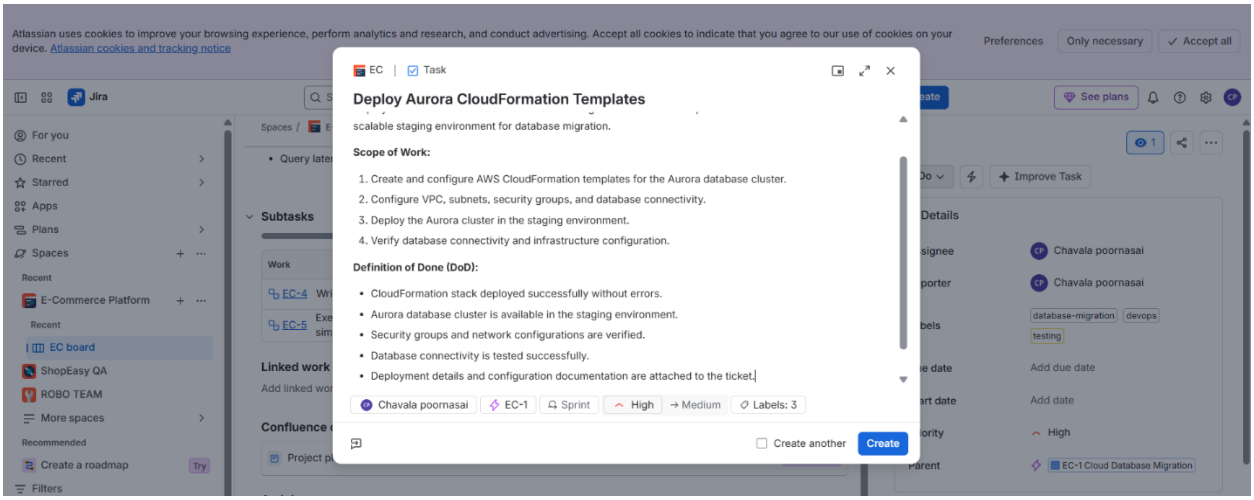

Manually added Sub task -2 to the above task:

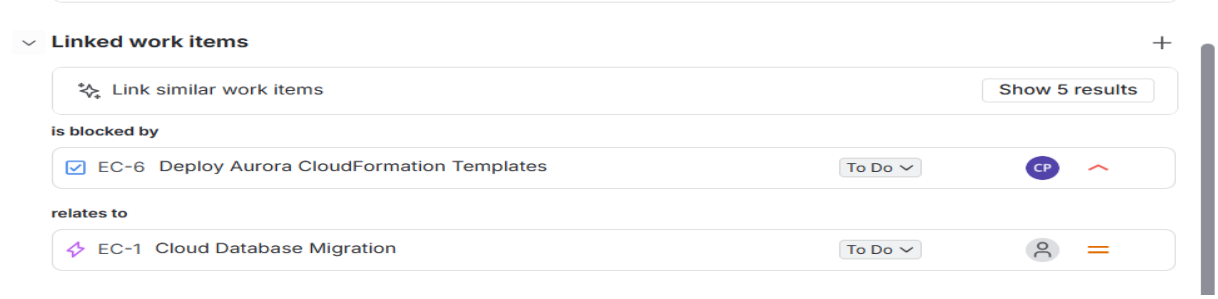

Created Another Task :

Name : Deploy Aurora CloudFormation Templates

Scope of work , Definition of Done .

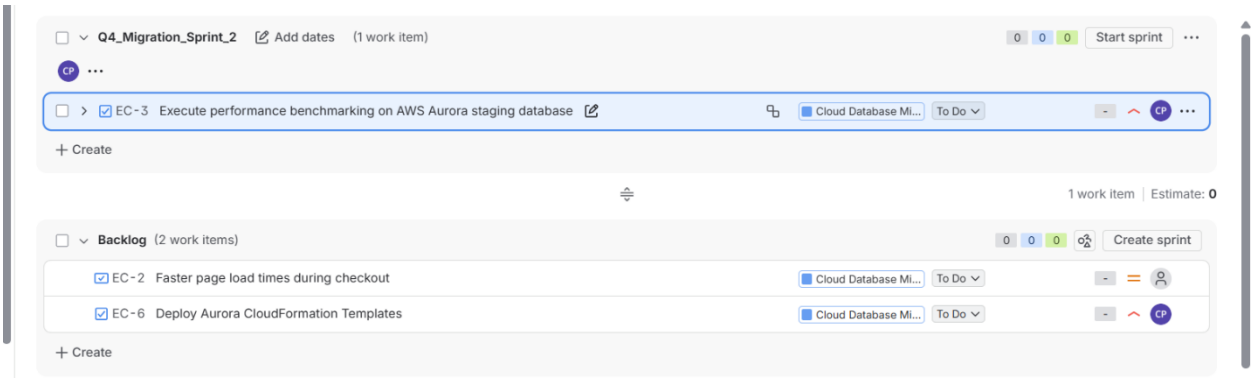

Linked the Epic to the above task

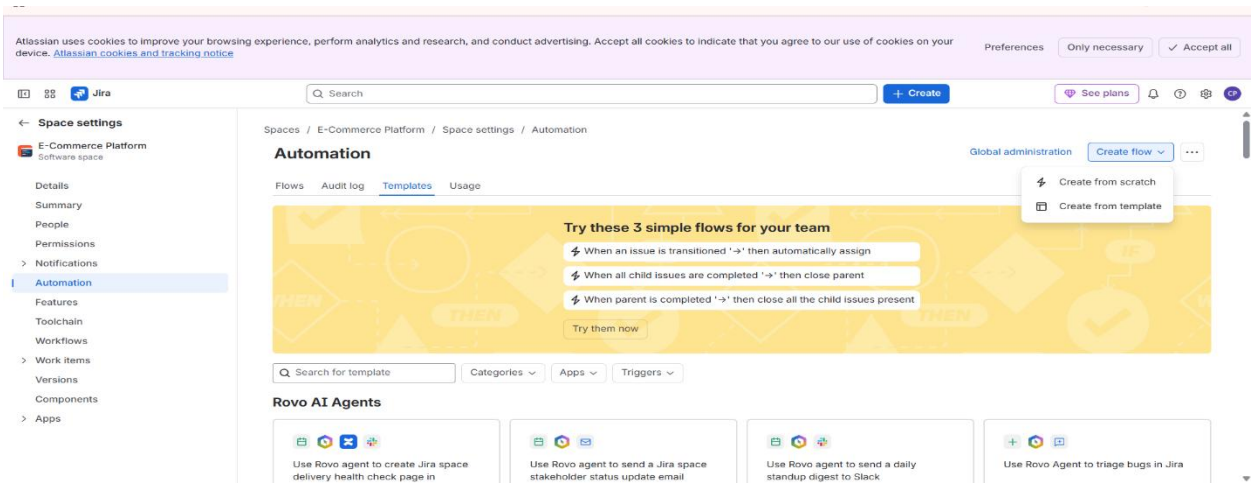

Created Sprint :

Name : Q4_Migration_Sprint_2

And added the task to the sprint .

Creating the Automation :

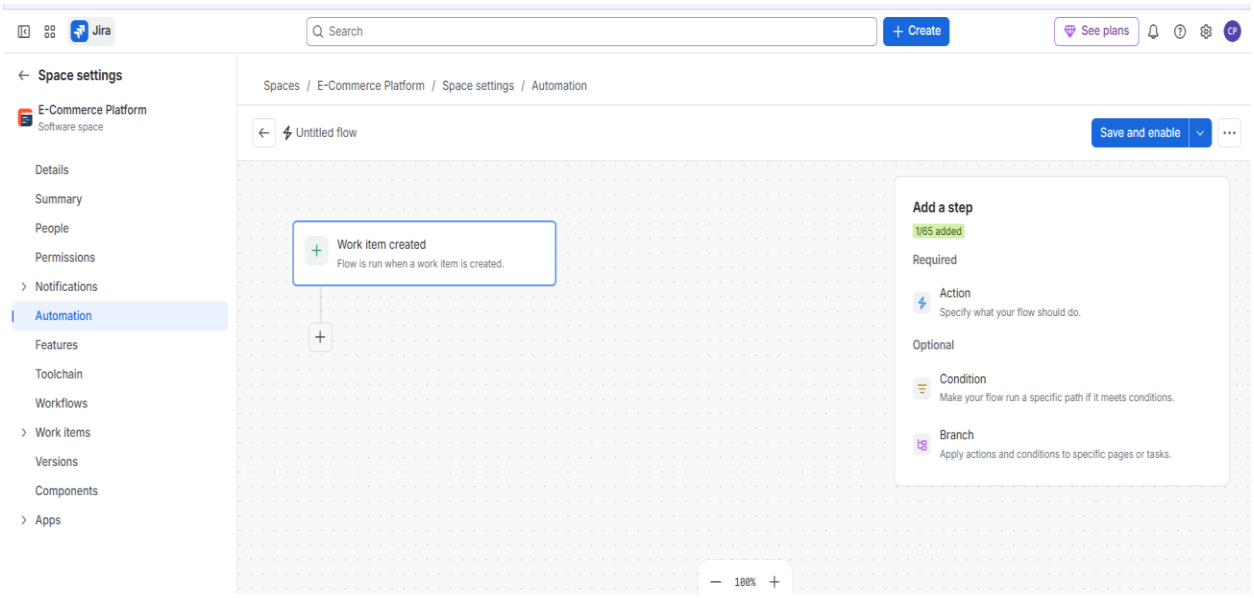

1. Trigger – Work item created: Whenever a new issue is created in your E-Commerce Platform project, Jira triggers the automation rule.

2. Condition – Issue Type: Jira checks whether the newly created issue is a standard Task.

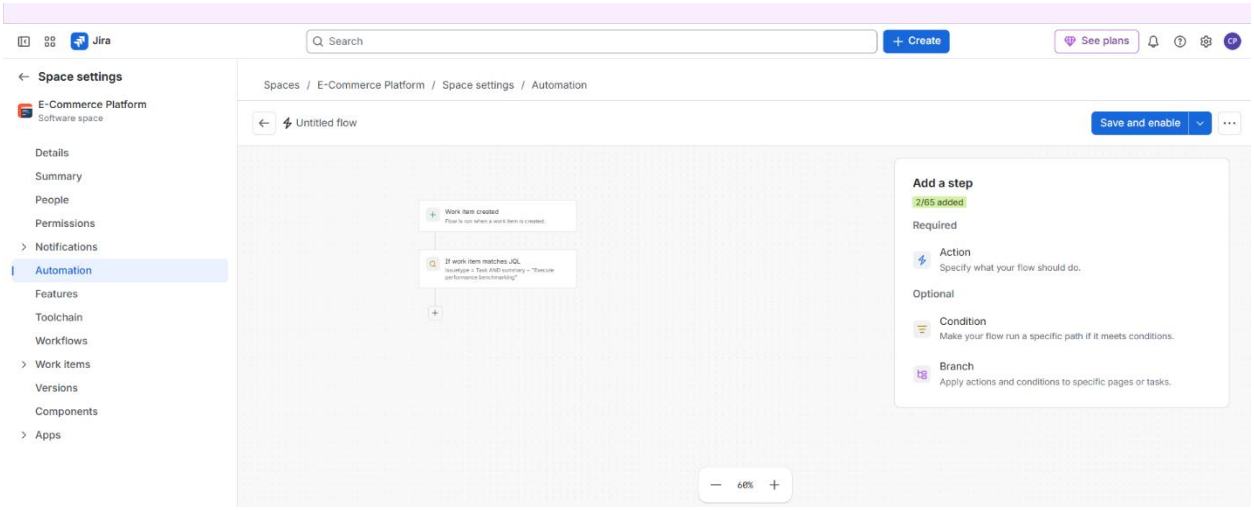

3. Condition – Summary: Jira checks whether its Summary contains Execute performance benchmarking.

4. Action – Create Sub-tasks: If both conditions are satisfied, Jira automatically creates:

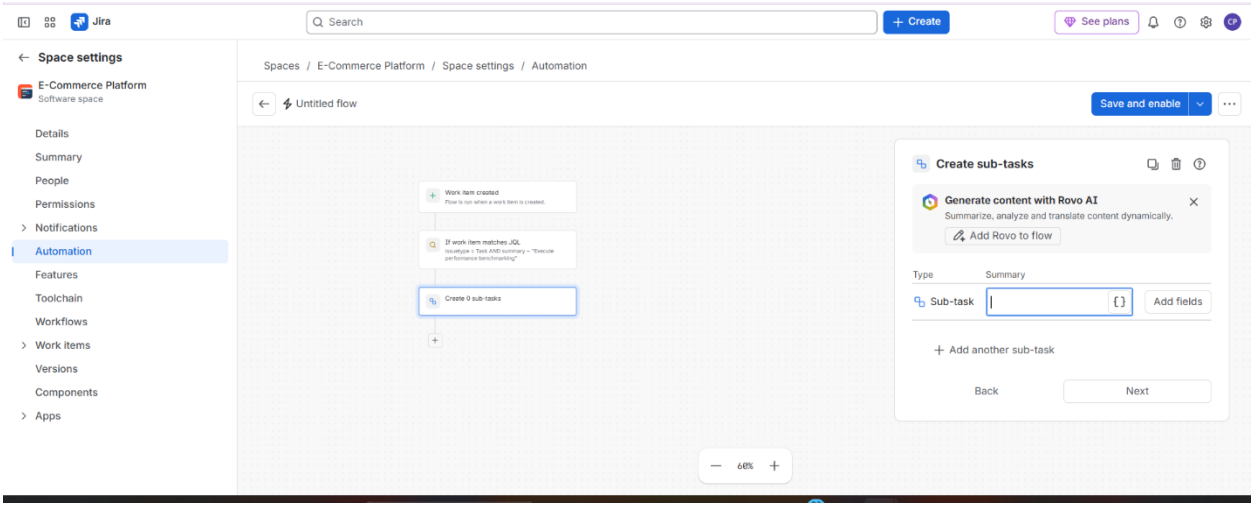

- Write automated load-testing scripts.
- Execute 10,000 concurrent user simulation.

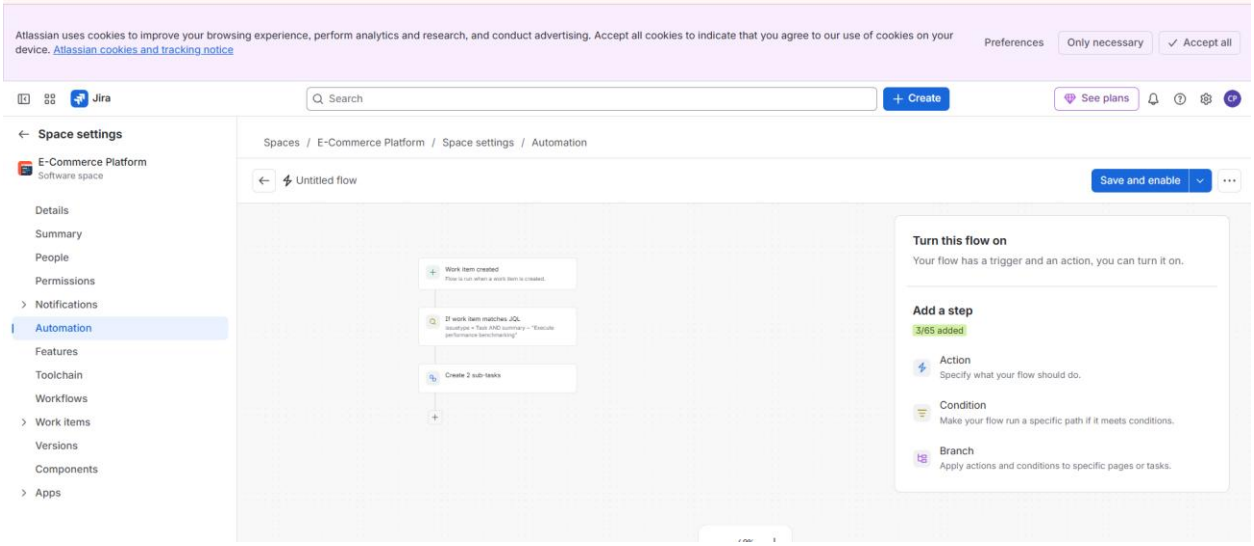

JQL QUERY : issuetype = Task AND summary ~ "Execute performance benchmarking"

Adding the sub-task for the automation:

The Jira Automation rule is configured with the Work Item Created trigger.
A JQL condition checks whether the issue type is Task and the summary contains the specified performance benchmarking text.
If both conditions are satisfied, Jira automatically creates two sub-tasks.
The automation flow is configured and can be activated using the Save and Enable option.

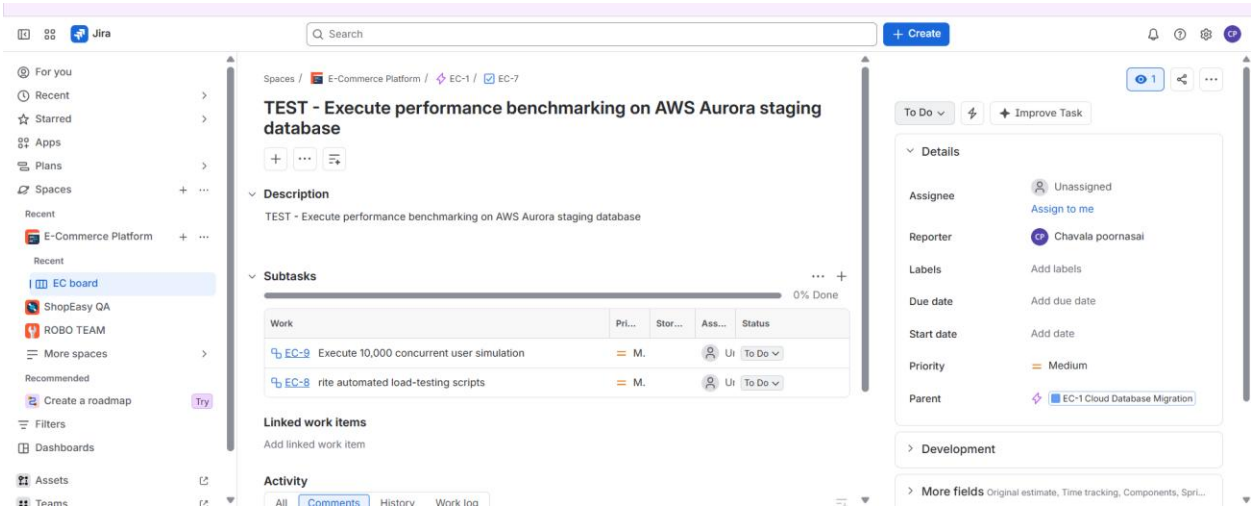

Whenever a new Task is created with the specified performance benchmarking summary, Jira automatically checks the issue type and summary. If both conditions match, it automatically creates two sub-tasks: Write automated load-testing scripts and Execute 10,000 concurrent user simulation under the newly created Task. This eliminates the need to create sub-tasks manually.

Now let’s check whether our automation is working correctly or not !!

We have to create the task and have to check whether are there any subtasks assigned to it or not ?

Created the Task :

Name : TEST - Execute performance benchmarking on AWS Aurora staging database .

As we can see there are 2 sub tasks assigned to the current task that means the automation is working correctly !!

---THANK YOU
